In English:

[0001] The numerical data transmission through a communication network is often carried out per packages. When the network is strictly transparent, it transmits the package as if it acted of an analogical signal, i.e. it does not fix each elementary period of bit of the package on a possible clock of the network. It is for example the case when they are simple cables, used, for example, in a network of diffusion at the request of programs of television, to transmit, at the station of head, the requests of the subscribers. This transmission can be carried out by using a temporal screen according to the technique TDMA (Multiple Access by Division of Time) in which one assigns a temporal way to each user. The transmissions can also relate to connections point-multipoint such as type LMDS (System of Multipoint Distribution Local)

In English:

[0002] So a receiver must, in control circuits of sampling, to initially analyze the shape of any signal received to recognize that it acts of a package and to determine one precise moment for which it is necessary to start to sample the signal recurringly, at the given rate/rhythm of the emission of the bits and, more generally, of symbols. It is thus necessary to manage to reproduce the clock having been used for the emission of the received symbols, and this with a delay corresponding exactly to the transmission, so, on the one hand, carrying out a logical synchronization to restore all the symbols of the package by locating the position of the first, and only those, and, on the other hand, to carry out an analogical synchronization, making it possible to correctly read each logical state of received symbol. Analogical synchronization requires to fix in phase sampling on the clock of emission, by holding account of the time of transmission, so that each symbol, whose reception started, is sampled with a sufficient delay to allow its stabilization and thus to read it without error. Obviously, logical synchronization can intervene only if analogical synchronization is established.

In English:

[0003] It is thus known to seek analogical synchronization, or synchronization on the rate/rhythm of the symbols, then to seek logical synchronization then, of the package, according to a predetermined preamble, to locate the position of the first symbol and thus those of the following according to the rate/rhythm. However, if the packages are low length, their preamble is also length limited in order to avoid a proportionally excessive loss of time of transmission, so that there remains a risk of defect of synchronization symbol and thus of nonlogical synchronization.

In English:

[0009] The receiver of figure 1 belongs to a station network head of a network of diffusion at the request of programs of television and comprises a stage of entry 1, of filtrage/demodulation of a signal $y(t)$, coming from a coaxial cable of a network of transmission, for which a more detailed explanation is provided further. The signal received $y(t)$ corresponds to a succession of requests of subscribers, distributed in temporal ways of a screen **TDMA**, selecting a particular program. Each request consists of a **package R of symbols** with a preamble predetermined P_r of recognition and synchronization, of P_r duration. When an subscriber wants to transmit a request, it to him is allocated an interval of time IT , or sees temporal, in the temporal screen repeating itself recurrently, the interval of time IT having one duration equal to that of a package R increased by a margin M , or interval of guard, to tolerate fluctuations of the moment of emission of the package R and to take into account the time of transmission.

In English:

[0017] In this example, one works out, in block 6, a flow of values of power of the Do data of beginning of package and, in block 5, a flow of values of correlation between the preamble predetermined Pr and the received preamble, by a continuous calculation of the current prices considered, the flow of values of correlation, being delayed D to add it with flow with values with power and thus to obtain a value of probability. [0018] As indicated higher, in this example the packages, of determined duration, are transmitted, without coordination between them, in the intervals of respective times IT of the temporal screen, intervals of time IT of duration corresponding to that of a package R increased by the margin Mr. One carries out a synchronization specific to each interval of time IT in a temporal window starting at the beginning of this one and including the margin M, i.e. one considers that the package R can be fixed at the end of the interval of time, the margin M being then entirely before the package R. [0019] The search for a maximum in circuit 8 is carried out continuously, i.e. the signal x(t) runs out in the various circuits and it is analyzed throughout this flow. For a digital processing, the samples of the signal x(t) are quantified on a given number of bits, for example 10 bits.

In English:

[0020] In this example, the analysis is carried out in a numerical way in a microprocessor DSP, or a ASIC or programmable logical circuit, so well the signal $x(t)$ is sampled here, for analysis, at a frequency of F_s oversampling higher than its frequency F of transmission, for example $K = \text{eight times this frequency } F$. The eight samples taken over one period T of a transmitted symbol then represent sufficiently accurately the received signal, an interpolation being moreover possible. The delay circuits 2 and 4 can thus be numerical, containing integrated memories. It is not besides necessary that the frequency of F_s oversampling is a multiple entirety of the frequency of emission of the symbols, i.e. unit 10 can have a frequency of autonomous operation, only the base of time 9 being related to the frequency of emission F . [0021] The determination of correlation of block 5 conforms to the following equation: EMI6.1 with I : row of the symbol in the package, here in the S^*i preamble: combined complex representation of the reason for symbols of ~~predetermined preamble~~. LP: a number of symbols of the preamble, here = 16. T: current moment.

In English:

[0022] Like higher exposed, there are in fact eight times more stages of calculation than reveals it the formula above, since there are here eight samples per symbol of duration T. [0023] The calculation of power in block 6 answers the equation: EMI6.2 with L (here: 252): a number of symbols of the preamble Pr and the zone C, this calculation thus relating only to this zone. [0024] One will note that calculations of blocks 5 and 6 can, in alternative, to relate to formulas as indicated but with an exhibitor whom can be other than 2, and for example being worth 1, the two choices of the values of exhibitor being independent from one formula to another, but preferably equal. In a general way, any increasing function according to the module of the variable is appropriate.

In English:

0025] interval 1 at L represents a temporal window of analysis of the signal received $x(t)$, window which this one crosses gradually as time passes. In other words, the window of analysis slips during one larger time of time $(M + L)$, in which the beginning of a package is awaited. [0026] Figure 3 illustrates the logic design of block 6 of calculation of power. As it is a question of recurringly calculating, at the frequency of oversampling F_s , a sum slipping on a plurality of terms, kind $I_f = x_0 + x_1 + \dots + x_{n-1}$ then, the following time: $I_{f+1} = x_1 + \dots + x_{n-1} + x_n$ one calculates simply $I_{f+1} = I_f - x_0 + x_n$ thus in two operations of correction of the preceding value I_f . [0027] Thus, one calculates the new current price recurringly I_{f+1} of power in the temporal window of given size L which the signals $x(t)$ cross, by memorizing the preceding value beforehand I_f and by correcting it according to the difference $x_n - x_0$ powers of the two sections of signals respectively entered and left the window L, of a calculation to the following.

[Help](#)

In English:

[0028] To this end, the entering signal is applied to an arithmetic unit 61 carrying out the addition above (If) and is also applied, through a circuit 62 with delay corresponding to the window of analysis, with an arithmetic unit 63 similar to block 61. A subtracter 64, supplied with circuits 61 and 63, provides the value $x_n - x_0$ to an adder 65 whose exit, which is that of block 6, is rebouclée in entry through a line of $K =$ eight shift registers 66 advancing at the frequency of F_s oversampling, thus corresponding to a total delay of one period T of symbol. Eight registers 66 make it possible to interlace K temporally = eight series of calculations, carrying each one on a specific phase of the signal analyzed during the time T . Ainsi, one carries out calculations of power per step at the frequency of multiple F_s oversampling (K) of the rate/rhythm of transmission F , by recurringly affecting, with each calculation, a temporal section during the time of the rate/rhythm T , and one restores the preceding value I_f by delaying it of a number of step equal to multiple K and representing on the whole the period T . Ainsi, adder 65 receives, to calculate $I_f + 1$, the signal I_f delayed T and the correction $x_n - x_0$.

In English:

wanted. [0029] In circuit 8, one detects the maximum of probability by cyclic comparisons between the current value and the preceding value of the probability provided by adder 7, for each time selecting the highest value and memorizing it, and one detects the maximum by the fact that the preceding value is again selected. [0030] More precisely, detector 8 of maximum, or peak, comprises a comparator of entry 81 and one multiplexer 82 to two ways receiving both, at the frequency of oversampling F_s , the new result of adder 7 and the preceding result coming from a delay circuit 83, with delay equal to the period of the frequency of F_s oversampling, is $T/8$ here. [0031] The exit of comparator 81, orders the shunting of multiplexer 82 to apply, with the entry of the delay circuit 83, the new result, current, as long as grows the analyzed signal coming from adder 7, and, if not, comparator 81 changes state to confirm the old result.

Help

In English:

[0033] A maximum is then detected when the memorized provisional maximum (83) is rebouclé (82) first once (milked reinforced), the exit of comparator 81 indicating a refusal of the current signal and thus a moment of beginning of repercussion of the signal summons, making it possible to launch the base of time 9. The search for maximum is continued here on all the window of time in order to obtain the total maximum. In the absence of useful signals, one eliminates from the parasitic maximas, due to noise, the fact that they do not exceed a minimum threshold. As the signal received x(t) is temporarily memorized in the delay circuit 2, this memorizing authorizes, without loss of the received signal, the prolongation of the analysis as a whole 10 beyond the moment to which one is detected (first) maximum. To delimit to better the total maximum, one can envisage to carry out the research of the maximum of probability on the totality of the package and possibly beyond, it be-with-statement which the Do zone represents then the totality of the package, except the preamble Pr, with, in end, a possible final section free from signals.

In English:

[0034] One thus works out the maximum of probability from suréchantillons whose flow contains, subjacent, information of rate/rhythm of the symbols and position of the first symbol to be detected, information which is used simultaneously and not sequentially as in art former mentioned to the beginning. Obtaining the maximum of probability provides then, in a total continuous stage, simultaneously, in form clarifies, here numerical, the phase symbol and the position of the first signal useful to sample. Thus, one deduces directly, according to the moment to which occurs the maximum of probability, at the same time the phase of the signals received at the known as rate/rhythm and the temporal position of the data in those.

[0035] The base of time 9 comprises an oscillator at period definitely lower than T, for example of frequency Fs, but then multiple entirety of the frequency F of emission of the symbols of x(t).

Babel Fish Translation

[Help](#)

In English:

[0039] In all the cases, the signal $x(t)$ is memorized, in analogical form or numerical form after digitalization by an oversampling making it possible to restore the form of it. One thus stores the total form, continues, of the signal $x(t)$ received, without seeking to detect there the symbols transmitted to frequency F , and it is only after the treatments above that one carries out sampling corresponding to the frequency F . As the signal $x(t)$ is memorized, time does not play more directly and one conceives that the concept of sampling at frequency F then includes the concept of space sampling in the memory, among suréchantillons, at one unspecified moment compared to the remainder of the data of the package R , which, with the choice, can be sampled as they arrive of circuit 1, without delay (2). [0040] In a case where each symbol would be represented by an evolutionary signal not in baseband, it would then be advisable to locate in circuit 2, according to the ordering of the base of time 9, the eights suréchantillons of each symbol to transmit them grouped to the circuit of sampling 3, at end of analysis, by demodulation to recognize the symbol.
